Supervision - Monitoring

Lucas Nussbaum
lucas.nussbaum@univ-lorraine.fr

Licence professionnelle ASRALL

Administration de systèmes, réseaux et applications à base de logiciels libres
Yes, this course is in English

- I will speak in French though
- Goal: get you used to reading technical documentation in English

This module:

- 6 slots of 3 hours
- Evaluation: practical work (*TPs*) + possibly exam
- Goals:
  - General knowledge of *infrastructure monitoring*
  - Master standard tools of the field
  - Know about the current trends in this field (e.g. impact of cloud and elasticity)

The other part of this module (*Supervision - Annuaire*) is totally independent (and with a different tutor: *Fabien Pascale*)
Introduction

- Success criteria for sysadmins: infrastructure that *just works*
  - Avoid incidents if possible
  - If not possible, minimize downtime

- How? Well-designed infrastructure
  - Choose reliable technologies and software
  - Add HA (*high-availability*), failover, redundancy, etc.

- Not enough: Murphy’s law (*Anything that can go wrong will go wrong*)

- Monitoring:
  - Collect information about the state of the infrastructure
  - Detect problems (before users have to report them)
  - Predict problems

  ~ Usual components:
  - Probes to acquire data
  - Database to store all measurements
  - Dashboard to show results
  - Notification system (email, SMS, etc.)
Example: Icinga

Example: graph from Munin

- Disk usage on a server
Two sides of the same coin: Metrology

Goal: collect lots of **metrics about how the system behaves** to track performance of the system over time \(\sim \text{telemetry}\)

- **Example:** collect statistics about network traffic, HTTP req/s, disk I/Os, ...
- **Required for performance analysis**
  - **USE method**
    - When there’s a performance problem, check for each resource: Utilisation, Saturation, Errors
  - **Also related to the RED method**
    - When there’s a performance problem, check for each service: Rate (number of req/s), Errors (number of failing req/s), Duration
  - **Also related to the four golden signals** (Latency, Traffic, Errors, Saturation)

\(\sim \) You need to keep track of all those metrics to be able to answer *is this the expected/usual value?*
Two sides of the same coin: Monitoring

Goal: actively check the system to verify that it works as expected, and to detect problems before users report them

- Example: issue a request to a web server, to check that it answers correctly
- Usually service-oriented, not really resource-oriented
  - Sometimes active checks that a resource’ value are within limits
There’s some disagreement about the terminology

- Supervision = Metrology + Monitoring ?
- Supervision = Monitoring ?
- Monitoring = Supervision + Metrology ?

The names are not very important, but it’s important to know the difference because software solutions usually focus on one of the two sides

- Metrology: **Munin**, Cacti, Ganglia, collectd, ...
- Monitoring: **Nagios**, check_MK, Icinga, Shinken, ...
Supervision is related to other topics

... which are not covered in this course

- Systems inventory / IT assets management
  - Database of all servers, network equipment, etc.
  - Example setup: GLPI (*Gestion Libre de Parc Informatique*), with a FusionInventory agent running on systems (to be seen in *Outils Libres côté serveur*)
  - Another example: LibreNMS (auto-discovery and monitoring of network equipment)

- Configuration Management Database (CMDB), services directory
  - Database about an information system: services, and how they are deployed
  - Typical solutions: Consul, iTop
  - Can be used as a source for the monitoring system (to get the list of services to monitor)

- Tools to manage (configure) the infrastructure: Puppet, Ansible, etc.
  - To be seen in *Gestion d'infrastructures*
Other aspects of monitoring

... also not covered in this course

▶ Security-oriented monitoring
  ♦ Intrusion Detection Systems (IDS)
    ★ Examples: Suricata (network), chkrootkit (systems)

▶ Log files analysis
  ♦ Gather all logs in a central place and analyze them
  ♦ Typical solutions:
    ★ Syslog (see Exposé technique)
    ★ logcheck
    ★ Graylog
    ★ Splunk
    ★ ELK (Logstash → ElasticSearch → Kibana)
Outline of this course

1. Introduction
2. Metrology & Munin
3. Monitoring with Icinga
4. SNMP
Reminder: see slide 6
Historical root: MRTG

- https://oss.oetiker.ch/mrtg/
- Multi Router Traffic Grapher
- Developed by Tobias Oetiker, first version in 1995
- Focus on monitoring network devices using SNMP
Common foundation: RRDTOOL

- 1999: Tobias Oetiker started the development of RRDTOOL
- https://oss.oetiker.ch/rrdtool/
- Much more flexible than MRTG
- Used for data storage and graphing by many metrology solutions: Cacti, collectd, Munin, Smokeping, ...

![Graph Example](image.png)
Landscape of metrology solutions

  - Implemented in Perl
  - Simple architecture, configured through configuration files
  - Easy to extend through plugins

- **Cacti** – [https://www.cacti.net/](https://www.cacti.net/)
  - Implemented in PHP
  - More focused on monitoring network traffic
  - Complex application; configuration using web interface; multi-user

- **collectd** – [https://collectd.org/](https://collectd.org/)
  - Implemented in C ~ fast ~ popular in low-power devices
  - Many plugins
  - Does not include a web frontend, but third-party projects do

- **Ganglia** – [http://ganglia.info/](http://ganglia.info/)
  - Focused on monitoring clusters of servers
    - Aggregate metrics for groups of servers
    - Originally from the High Performance Computing world
Landscape of metrology solutions (2)

- **Graphite** – [https://graphiteapp.org/](https://graphiteapp.org/)
  - Not based on RRDTOOL
  - Does not handle data collection, only storage and graphing
  - Can be used with collectd (for collection), or many other tools

- **Prometheus** – [https://prometheus.io/](https://prometheus.io/)
  - Modern solution, suited to elastic infrastructures
  - Dynamic aggregation of metrics
  - Alerting based on metrics
  - Videos:
    - [Prometheus - A Next Generation Monitoring System](https://prometheus.io/docs) (FOSDEM 2016)
    - [Alerting with Time Series](https://prometheus.io/docs) (FOSDEM 2017)
    - Deploying Prometheus at Wikimedia Foundation (FOSDEM 2017)
    - Evolving Prometheus for the Cloud Native World (FOSDEM 2018)

- **Summary of the current status:**
  - Prometheus looks like the future (but is still a young project)
  - Traditional solutions are still very much used in production, especially on traditional infrastructures → **focus on Munin in this course**
Munin

- http://munin-monitoring.org/
  - Documentation: http://guide.munin-monitoring.org
- Implemented in Perl
- Simple and robust
- Configured through configuration files (/etc/munin/)
- Easy to extend through plugins (in any language)
- Generates static pages and graphs, no access control
  - Graphs can also be generated using a CGI script
- Basic alerting (warning/critical thresholds)
- Video: Alexandre Simon, Luc Didry. Munin : superviser simplement la machine à café ... enfin une réalité ! (JRES 2013)
- Example instances:
  - Debian: https://munin.debian.org/ (dsa-guest / dsa-guest)
  - Framasoft: munin data exported to Grafana, with many custom plugins (see blog from Luc Didry) : link
Munin web interface

Munin architecture

Munin architecture (2)

- **Munin node**
  - sur les machines à superviser
  - serveur écoutant sur 4949/TCP
  - exécute des *plugins* à la demande du maître

source: talk at JRES 2013 (see before)
Munin architecture (3)

- **Munin master**
  - le “superviseur”
  - instance surveillant 1 ou plusieurs nœuds
  - client se connectant sur le 4949/TCP des nœuds, fait exécuter les *plugins*
  - archive la collecte et génère les graphes
  - publie les pages HTML et les graphes

source: talk at JRES 2013 (see before)
Munin installation notes

▶ On nodes: `apt install munin-node`
  ♦ By default, it only allows the local machine to connect

▶ On the master: `apt install munin`
  ♦ Munin runs in a cron job, see `/etc/cron.d/munin`
  ♦ Target nodes must be added to `/etc/munin/munin.conf` or `/etc/munin/munin.conf.d/*`
  ♦ Install a web server to expose files generated by Munin. Munin provides an example configuration file for Apache, so:
    ★ `apt install apache2`
    ★ `ln -s /etc/munin/apache24.conf /etc/apache2/conf-enabled/`
    ★ Allow all addresses to connect: in `/etc/munin/apache24.conf`, change `require local` to `require all granted`
    ★ `service apache2 restart`

▶ Additional plugins are configured in `/etc/munin/plugins`
  ♦ To get suggestions about which plugins to configure: `munin-node-configure --suggest` (or `--shell`)
  ♦ Restart munin-node when its configuration is changed
Troubleshooting

- Logs are in `/var/log/munin/` (for example: `/var/log/munin/munin-update.log` for the log describing what happens when the munin master tries to contact munin nodes)

- You can run the cron job manually using `sudo -u munin munin-cron`
  - You can force the generation of HTML pages using:
    `sudo -u munin /usr/share/munin/munin-html --debug`
  - You can force the generation of graphs using:
    `sudo -u munin /usr/share/munin/munin-graph --debug --nofork --nolazy`

- You can debug munin-node by connecting to it using `telnet` on port 4949. Just send junk to get the list of commands.
  - It is a good way to check whether the munin master can talk to munin nodes.

- The default update rate is 5 minutes. You can reduce it to one minute:
  - Add `update_rate 60` to `/etc/munin/munin.conf`
  - Change `/etc/cron.d/munin` so that it runs every minute
  - Remove all files in `/var/lib/munin/`
Writing Munin plugins

- Simple scripts, to be placed in /etc/munin/plugins

- With the config parameter, must display the configuration:

  ```
  # /etc/munin/plugins/threads config
  graph_title Number of threads
  graph_vlabel number of threads
  graph_category processes
  graph_info This graph shows the number of threads.
  threads.label threads
  threads.info The current number of threads.
  ```

- Without parameter, must display the value:

  ```
  # /etc/munin/plugins/threads
  threads.value 112
  ```

  - Also see the video from JRES 2013
TP 1
Monitor & Icinga

- Reminder: see slide 7
Side note: Open Core model

- **Principle:**
  - The central piece of the software is free software
  - Some features are for paying customers only

- **Variant:**
  - The software is free, but new versions (or even worse: security updates) are available first to paying customers

- **Example (outside of monitoring):** GitLab
  - Integrated development environment
    - ★ ≈ *libre GitHub*: Git + bug tracker + CI + ...
  - *Community* version free (as in freedom and as in beer)
  - Other versions available for a fee, with added features
Common ancestor: Nagios

- Initiated in 1999 (under the *NetSaint* name)
- Around 2009: dissatisfaction in the community about the project management → forks (Icinga, etc.)
- Now developed by Nagios Enterprises using an Open Core model
  - The core software is now named *Nagios Core*
- Features:
  - Monitoring of hosts
  - Monitoring of hosts resources (but not as detailed as Munin, and without good history by default)
  - Monitoring of services
  - Many plugins available
  - Ability to run remote scripts using NRPE (*Nagios Remote Plugin Executor*)
Landscape of Monitoring solutions

- **Icinga** – https://icinga.com/
  - Forked from Nagios in 2009
  - Version 1 was strongly based on Nagios
    - See those slides from RMLL 2011 about Icinga
  - Version 2 is a rewrite
    - See this video about Icinga 2

- **Check_MK** – https://mathias-kettner.com/
  - Initially started as a Nagios extension to improve scalability
  - Now a standalone monitoring solution

- **Shinken** – http://www.shinken-monitoring.org/
  - Rewrite of Nagios in Python
  - See this talk from RMLL 2010 for an introduction to Shinken
  - Dead project?
Landscape of Monitoring solutions (2)

  - Appliance – useful in mixed Windows/Linux environments, or when the monitoring system is the only Linux system in the infrastructure

- Centreon – [https://www.centreon.com/](https://www.centreon.com/)
  - Another appliance solution
  - French company – popular in French infrastructures
  - Open Core
Nagvis – http://www.nagvis.org/

- Nagios addon to provide graphical representations using the hierarchy of hosts and services
Current status of Monitoring

- Many Nagios-like solutions
  - Some of them are forks of Nagios, some of them are rewrites
  - Some of them are Open Core
  - Not clear which one will win, especially since many of them are company-backed

- Focus in this course: Icinga 1.x
  - Nagios-compatible, but still better than Nagios
    - Note: Icinga 2.x is very different from Icinga 1.x
  - In terms of spirit, it is fairly Free software
  - Concepts of all those solutions are similar anyway

- Also, important to keep an eye on modern solutions such as Prometheus
Icinga 1.x

- Most of what you can read about Nagios is true for Icinga 1.x
- Icinga documentation: https://icinga.com/docs/icinga1/latest/en/
- Components:
  - Icinga Core – the core software
  - Icinga classic Web UI is a CGI-based interface
    - It reads the status of Icinga from /var/lib/icinga/status.dat
    - It can submit changes to the core using /var/lib/icinga/rw/
  - IDODB (Icinga Data Out Database) is a database used to store results. It is required for the new Web UI (not used in this course)
  - Plugins (for checks) are in /usr/lib/nagios/plugins/ (from the monitoring-plugins-* packages)
    - See /etc/nagios-plugins/config/ for their command definitions
  - NRPE (Nagios Remote Plugin Execution) is used to run checks on remote hosts
    - nagios-nrpe-plugin must be installed on the master node, and nagios-nrpe-server must be installed on the slave nodes
  - NSCA (Nagios Service Check Acceptor) is used to receive data for passive checks
More information about Nagios & Icinga

- MOOC *Supervision de Réseaux et Services*
  - [https://www.fun-mooc.fr/courses/course-v1:lorraine+30008+session02/about](https://www.fun-mooc.fr/courses/course-v1:lorraine+30008+session02/about)

- Videos available from

- Specifically *Semaine 2* (total of 45 minutes)
Icinga installation

- Install Icinga: `apt-get install icinga`
  - Enable external commands (used to trigger actions from the web interface)
- The classic Web UI should be available at `http://ops.local/icinga/` in the Vagrant environment
  - By default, it monitors the local machine
Icinga configuration

- In /etc/icinga/
- Object-oriented: inheritance, classes (groups) of hosts/services/contacts
- Main objects: hosts, services
- Basic example:

```plaintext
define host {
    use generic-host ; generic-host is a template
    host_name web.local
    alias web
}

define service {
    use generic-service ; generic-service is a template
    host_name web.local ; host(s) for this service
    service_description HTTP
    check_command check_http
}
```
Icinga configuration (2)

- Using hostgroups to group similar hosts

```plaintext
define hostgroup {
    hostgroup_name http-servers
    alias HTTP servers
    members localhost web.local
}
define service {
    hostgroup_name http-servers
    service_description HTTP
    check_command check_http
    use generic-service
}
```
Icinga configuration (3)

- Check commands can use parameters
- For example `check_http2` (with VHost, warning delay, critical delay)
  (see https://www.monitoring-plugins.org/doc/man/check_http.html)
- In `/etc/nagios-plugins/config/http.cfg`:

```plaintext
define command {
    command_name    check_http2
    command_line    
        /usr/lib/nagios/plugins/check_http -H ' $ARG1$' -I 'HOSTADDRESS$' -w '$ARG2$' -c '$ARG3$' ' $ARG4$'
}
```

- Service definition:

```plaintext
define service {
    use generic-service
    host_name    webserver
    service_description HTTP
    check_command check_http2!www.myvhost.com!5!10
}
```
Icinga configuration: other objects

- Host, Hostgroup
- Service, Servicegroup
- Contact, Contactgroup
- Timeperiod
- Command
- Servicedependency
- Serviceescalation
- Hostdependency
- Hostescalation
- Hostextinfo
- Serviceextinfo
- Module

NRPE (Nagios Remote Plugin Execution)

- **Problem:** all checks are run from the Icinga machine
  - ♦ How can we test things that are not visible from a remote machine?
- **Server running on remote hosts that answers requests from check_nrpe**
- **Installation:**
  - ♦ On the Icinga machine: nagios-nrpe-plugin (provides check_nrpe)
  - ♦ On the target machine: nagios-nrpe-server
    - ★ By default, only 127.0.0.1 is allowed to connect
- **Documentation:**
NRPE Configuration

- On the target host, in /etc/nagios/nrpe*
  - Command definition example:
    ```
    command[check_users]=/usr/lib/nagios/plugins/check_users -w 5 -c 10
    ```

- On the Icinga machine:
  ```
  define service {
    use generic-service
    host_name web.local
    service_description Current users
    check_command check_nrpe!check_users
  }
  ```
Writing Icinga plugins

- Simple scripts or compiled programs
- Documentation:
- Return code: 0 (OK), 1 (WARNING), 2 (CRITICAL), 3 (UNKNOWN)
- Output: see documentation. Example:
  DISK OK – free space: / 3326 MB (56%)
TP 2
SNMP

Simple **Network Management** Protocol

Three use cases (the first one is the only used frequently in practice):
- Get information from a device: the manager sends a request to the agent running on the managed device
- Configure a device (SNMP is sometimes a good way to automate things in scripts)
- Receive traps from the agent: typically, get notified when errors happen on the managed device

Typical compatible devices: routers, switches, printers, servers management cards (BMC, Baseboard Management Controller)
- SNMP = the standard protocol to retrieve information from those devices
- Also possible to install an SNMP agent on a server, but rarely done
MIB: Management Information Base

- Hierarchy of Managed Objects (MO)
- Each MO is identified by an Object Identifier (OID)
- Example: .1.3.6.1.2.1.1.3.0 = DISMAN-EVENT-MIB::sysUpTimeInstance
- Some parts are standard, some are vendor-specific
- Sub-trees are defined in additional MIBs

Basic use

- `snmpwalk -v 1 -c public remoteagent [OID]`
  - `-v 1` is the SNMP version to use (usually 1 or 2c)
  - `-c public` is the SNMP community to use. This is used similarly to a password

- Other useful options:
  - `-m ALL`: load all MIBs, not just the default set
  - `-O n`: display OIDs numerically
  - `-C c`: disable check for increasing OIDs

- Other useful command: `snmpget` (get a single OID)

- Examples:
  - `snmpwalk -v 2c -c public asrall-sw24 IF-MIB::ifMtu`
  - `snmpget -v 2c -c public asrall-sw24 IF-MIB::ifMtu.1`
Installing additional MIBs on Debian

- Make sure that the APT source for non-free is enabled
- Install the `snmp-mibs-downloader` package
- Comment the last line of `/etc/snmp/snmp.conf`
TP 3
Conclusions

- Monitoring is a critical element of any infrastructure
  - To detect problems before users
  - To prevent problems before they occur

- Two components:
  - Metrology: collect historical data about the infrastructure
    - Understand trends
  - Monitoring: check that the infrastructure works as expected

- Useful to have even if the rest of the infrastructure is not automated
  - But even better when you combine it with systems inventories, services directories, configuration management
