Towards a correctly-rounded and fast power function in binary64 arithmetic

Tom Hubrecht, Claude-Pierre Jeannerod, Paul Zimmermann

30th Arith conference, Portland, September 5th, 2023
$ cat test.c
#include <stdio.h>
#include <math.h>
int main () {
    double x = 0x1.0fbcd29b56829p-1;
    double y = 0x1.57347b643eac2p-1;
    printf ("x^y = %la\n", pow (x, y)); }
$ cc -fno-builtin test.c -lm

If you get 0x1.4ed9af3ea18c3p-1, maybe you are using the GNU libc.
If you get 0x1.4ed9af3ea18c4p-1, maybe you are using the Intel math library.
(The correctly rounded result is that of GNU libc in that case, but for
x = 0x1.30b3e414e3d3bp-1 and y = 0x1.a6c0a38da8066p-1 we get the converse.)
Previous Work

- books of Markstein and Beebe
- MathLib library (Ziv, 1991)
- LIBMCR (Sun, 2004)
- CRLIBM (De Dinechin, Lauter and al., 2006)
- more recently RLIBM and LLVM libc, but do not provide (yet) a binary64 power function
MathLib (-1991)

Only for rounding to nearest even.
Integrated in GNU libc, slow path removed after 2.27 (2018).
Algorithm is not detailed.
No longer maintained.
Non official copies still exist, no bug found.
Only for rounding to nearest even.
Algorithm is not detailed.
pow does not terminate for some inputs, for example $x=0x1.470574d68e0afp+1$, $y=0x1.02e0706205c0ep+1$.
Wrong results for some inputs, for example $x=0x1.f80b060553772p-1$ and $y=0x1.99cp+13$, gives $0x1.00001p+0$ instead of $0x1.a2e7cca9cfd72p-297$ (49 identical bits after the round bit).
No longer maintained.
CRLIBM (-2006)

Experimental, and only for rounding to nearest even.
Algorithm partially detailed in Lauter’s PhD thesis.
Wrong result for $x=0x1.524ebae943097p+1$ and $y=0x1.ep^{-2}$, gives $-5$ instead of $0x1.93bd0cd47eb5fp+0$ (64 identical bits after the round bit).
No longer maintained.
Our contribution

- an open-source implementation, integrated into CORE-MATH
- covers all IEEE 754 rounding modes, not only to nearest-even
- an extended paper with full proofs of the 1st phase
- full details of the 2nd and 3rd phases with the code
- performance: outperforms previous work, not far from incorrectly rounded math libraries

In the Arith proceedings you find the 8-page short version, with detailed algorithms for the 1st phase, lemmas and theorems, but without proofs.

On https://inria.hal.science/hal-04159652 you find the long version, with a 14-pages appendix containing detailed proofs. This version will be kept up-to-date with further improvements.
Performance

Intel Core i7-8700 cycles with GCC 12.2.0, rounding to nearest-even:

How to compute $x^y$?

Using $x^y = 2^y \log_2 x$ (Markstein, Beebe) looks quite interesting, but the Taylor expansions of $\log_2(1 + t)$ and $2^t$ at $t = 0$ have less simple coefficients.

We prefer to use $x^y = e^{y \log x}$, with more complex argument reduction, but simpler Taylor expansions.
Exact and midpoint cases

$x^y$ is exact if exactly representable in binary64.

$x^y$ is midpoint if exactly representable with 54 bits (but not with 53).

Detecting and dealing with exact/midpoint cases is crucial.

Efficient algorithms from Lauter and Lefèvre (2009).
Workflow

1. 1st phase computes double-double approximation; if rounding test succeeds, return result
2. 2nd phase computes approximation with 128-bit arithmetic; if rounding test succeeds, return result; otherwise, check for exact/midpoint cases
3. 3rd phase computes approximation with 256-bit arithmetic; if rounding test succeeds, return result; otherwise, print error message
Notations

We denote by \( o(a + b) \) or \( o(a \cdot b) \) the correct rounding (with the current rounding mode) of \( a + b \) and \( a \cdot b \) respectively.

We denote by \( o(a \cdot b + c) \) the correct rounding of \( a \cdot b + c \), which can be efficiently computed with an FMA (fused-multiply-add) if available in hardware, or emulated in software (\_\_builtin\_fma).
Theorem (Zimmermann, 2023)

Whatever the IEEE 754 rounding mode, in the absence of underflow/overflow, the output $h, \ell$ of FastTwoSum satisfies

$$|h + \ell - (a + b)| \leq 2^{-105}|h|,$$

and if the exponents of $a, b$ differ by at most 53, $h + \ell = a + b$. 
FastSum

**Input:** $a, b_h, b_\ell \in \mathbb{F}$ with $a = 0$ or $|a| \geq |b_h|$

**Output:** $h, \ell$ such that $h + \ell$ approximates $a + b_h + b_\ell$

1: $h, t \leftarrow \text{FastTwoSum}(a, b_h)$
2: $\ell \leftarrow \circ(t + b_\ell)$

**Lemma**

In no underflow nor overflow, the pair $(h, \ell)$ computed by Algorithm FastSum satisfies

$$|h + \ell - (a + b_h + b_\ell)| \leq 2^{-105} |h| + \text{ulp}(\ell).$$
Approximation of $\log(1 + z)$ around zero

Algorithm 1 Algorithm p_1

Input: $z \in \mathbb{F}$, $|z| \leq 33 \cdot 2^{-13}$

Output: $p_h + p_\ell$ approximating $\log(1 + z) - z$

1: $w_h, w_\ell \leftarrow \text{ExactMul}(z, z)$
2: $t \leftarrow \circ(0x1.0001f0c80e8cep-3 \cdot z + 0x1.2494526fd4a06p-3)$
3: $u \leftarrow \circ(0x1.55555553d1eb4p-3 \cdot z + 0x1.999999981f535p-3)$
4: $v \leftarrow \circ(0x1.0000000000003p-2 \cdot z + 0x1.555555555555p-2)$
5: $u \leftarrow \circ(t w_h + u)$
6: $v \leftarrow \circ(u w_h + v)$
7: $u \leftarrow \circ(v w_h)$
8: $p_h \leftarrow -0.5 \cdot w_h$
9: $p_\ell \leftarrow \circ(u z - 0.5 \cdot w_\ell)$
Lemma

Given $|z| \leq 33 \cdot 2^{-13}$ with $z$ an integer multiple of $2^{-61}$, the double-double approximation $p_h + p_\ell$ to $\log(1+z) - z$ returned by Algorithm $p_1$ satisfies

$$|p_h + p_\ell - (\log(1+z) - z)| < 2^{-75.492},$$

with $|p_h| < 2^{-16.9}$ and $|p_\ell| < 2^{-25.446}$. If $z \neq 0$, and assuming further $|z| \leq 32 \cdot 2^{-13}$, the relative error satisfies

$$\left| \frac{z + p_h + p_\ell}{\log(1+z)} - 1 \right| < 2^{-67.441}.$$

Proved using the Coq proof assistant (by Laurence Rideau and Laurent Théry).
Approximation of log $x$

**Algorithm 2 Algorithm log_1**

**Input:** a binary64 value $x \in [\alpha, \Omega]$  
**Output:** $h + \ell$ approximating $\log x$

1: write $x = t \cdot 2^e$ with $t \in (1/\sqrt{2}, \sqrt{2})$ and $e \in \mathbb{Z}$  
2: $i \leftarrow \lfloor 2^8 t \rfloor$  
3: $r \leftarrow \text{INVERSE}_i$, $\ell_1, \ell_2 \leftarrow \text{LOGINV}_i$  
4: $z \leftarrow \circ (rt - 1)$  
5: $t_h \leftarrow \circ (e \text{LOG2H} + \ell_1)$  
6: $t_\ell \leftarrow \circ (e \text{LOG2L} + \ell_2)$  
7: $h, \ell \leftarrow \text{FastSum}(t_h, z, t_\ell)$  
8: $p_h, p_\ell \leftarrow \text{p}_1(z)$  
9: $h, \ell \leftarrow \text{FastSum}(h, p_h, \circ (\ell + p_\ell))$

10: if $e = 0$ and $|\ell| > 2^{-24}|h|$ then $h, \ell \leftarrow \text{FastTwoSum}(h, \ell)$
Lemma

Given $x \in [\alpha, \Omega]$, Algorithm log_1 computes $(h, \ell)$ such that $|\ell| \leq 2^{-23.89}|h|$, and

$$|h + \ell - \log x| \leq \varepsilon_{\log} \cdot |\log x|$$ (1)

with $\varepsilon_{\log} = 2^{-73.527}$ if $x \notin (1/\sqrt{2}, \sqrt{2})$, and $\varepsilon_{\log} = 2^{-67.0544}$ otherwise.

Proved using the Coq proof assistant (by Laurence Rideau and Laurent Théry).
Multiplication by $y$

**Input:** a double-double value $h + \ell$, and a double $y$

**Output:** $r_h + r_\ell$ approximating $y(h + \ell)$

1. $r_h, s \leftarrow \text{ExactMul}(y, h)$
2. $r_\ell \leftarrow o(y\ell + s)$

---

**Lemma**

If $x, h, \ell$ are as in previous Lemma and if $2^{-969} \leq |yh| \leq 709.7827$, then $(r_h, r_\ell)$ satisfy

$|r_h| \in [2^{-970}, 709.79], \ |r_\ell| \leq 2^{-14.4187}, \ |r_\ell/r_h| \leq 2^{-23.8899}, \ |r_h + r_\ell| \leq 709.79$, and

$$|r_h + r_\ell - y \log x| \leq \varepsilon_{mul}$$

with $\varepsilon_{mul} = 2^{-63.799}$ if $x \notin (1/\sqrt{2}, \sqrt{2})$, and $\varepsilon_{mul} = 2^{-57.580}$ otherwise.
Final exponentiation

See proceedings for details of Algorithm exp_1.

**Lemma**

In the case $\rho_1 \leq r_h \leq \rho_2$, if $|r_\ell / r_h| < 2^{-23.8899}$ and $|r_\ell| < 2^{-14.4187}$, then the value $e_h + e_\ell$ returned by Algorithm exp_1 satisfies

$$\left| \frac{e_h + e_\ell}{\exp(r_h + r_\ell)} - 1 \right| < 2^{-74.16}.$$

Moreover, $|e_\ell / e_h| \leq 2^{-41.7}$. 

Towards a correctly-rounded and fast power function in binary64 arithmetic 20/31
Main algorithm for 1st phase

**Input:** two binary64 numbers $x, y$ with $x > 0$

**Output:** the correct rounding of $x^y$, or FAIL

1: $\ell_h, \ell_\ell \leftarrow \log_1(x)$
2: $r_h, r_\ell \leftarrow \text{mul}_1(\ell_h, \ell_\ell, y)$
3: $e_h, e_\ell \leftarrow \text{exp}_1(r_h, r_\ell)$
4: if $\sqrt{2}/2 < x < \sqrt{2}$ then $\epsilon \leftarrow \text{RU}(2^{-57.579})$ else $\epsilon \leftarrow \text{RU}(2^{-63.797})$
5: $u \leftarrow \circ(e_h + \circ(e_\ell - \epsilon e_h)), v \leftarrow \circ(e_h + \circ(e_\ell + \epsilon e_h))$
6: if $u = v$ then return $u$ else return FAIL

**Theorem**

*The value returned by Algorithm phase_1 (if not FAIL) is correctly rounded.*
Main achievements

Our algorithms work for all IEEE 754 rounding modes.

Heavy use of FMA (either in hardware or emulated).

Crucial usage of FastTwoSum, with error bound for directed rounding modes.

Hardest to round inputs are not known for pow: 3rd phase might return an error message, but will not deliver any incorrectly-rounded result.

Code 2x to 4x faster than previous work.

All IEEE 754 specials cases are dealt with.

Very detailed proofs.

A major achievement since pow is the most difficult binary64 function.
Further work

The algorithms and code can be improved further (and we work on it).

Formal proof of the 1st phase in progress, thanks to Laurence Rideau and Laurent Théry, using the Coq proof assistant.

Simplify the formal proofs using tools presented by Paul Geneau de Lamarlière on Monday.

Approach scales for double-extended and quadruple precision.

An important step towards requiring correct rounding in IEEE 754-2029?
The following slides give reciprocal throughput and latency of CORE-MATH (commit 81d5ea0), GNU libc 2.37, the Intel math library with icx 2023.2.0 (with -fp-model=strict -fno-fast-math), and LLVM libc (revision d099dbb).

Hardware: Intel Xeon Silver 4214.

Compiler (except for Intel math library): gcc 13.2.0.
